Validation and reproducibility of new measurements {#Sec18}

----- In order to determine the clinical values of the new method, we analyzed the variation of the new method in the clinical laboratory of the Hospital Clinic of Barcelona. We performed the same measurements for blood from the same two healthy individuals (A and B) and analyzed them every 2 weeks. We repeated the measurements in different days of the week, in different seasons and in different months. In addition, we performed the same measurements in different days of the week for each individual, in different seasons and in different months. Finally, for each of the samples analyzed, we calculated the within-subject standard deviation (Fig. [1]{#Fig1}{ref-type="fig"}) and performed intraclass correlation coefficient (ICC) analysis for measurement values obtained using different days of the week, different seasons and different months. The ICC was used to measure the degree of concordance between the results of two observers. The ICC was used as a measure of reliability and consistency 82157476af
